

Solving Exponential Equations - Example 4

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

But we don't have the same base on both sides!

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

But we don't have the same base on both sides!

We have **base** 2 on left and 3 on the right

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

But we don't have the same base on both sides!

We have **base** 2 on left and 3 on the right

Can we get the same base on both sides like we did in ▶ Example 3?

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

But we don't have the same base on both sides!

We have **base** 2 on left and 3 on the right

Can we get the same base on both sides like we did in ▶ Example 3?

Unfortunately, it is difficult to find a number a so that $3 = 2^a$

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

But we don't have the same base on both sides!

We have **base** 2 on left and 3 on the right

Can we get the same base on both sides like we did in ▶ Example 3?

Unfortunately, it is difficult to find a number a so that $3 = 2^a$

And it is similarly difficult to write 2 as a power of 3.

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

But we don't have the same base on both sides!

We have **base** 2 on left and 3 on the right

Can we get the same base on both sides like we did in ▶ Example 3?

Unfortunately, it is difficult to find a number a so that $3 = 2^a$

And it is similarly difficult to write 2 as a power of 3.

Since our only method of solving exponential equations relies on writing both sides in the same base, we are stuck!

Solving Exponential Equations - Example 4

Example: Find solutions to the equation:

$$2^{(x+1)} = 3^x$$

▶ We saw that Exponential Functions are ▶ one-to-one

Which means that, if $c^a = c^b$ then $a = b$ because two different exponents cannot output the same value

To use this we need to have the same **base** on both sides.

But we don't have the same base on both sides!

We have **base** 2 on left and 3 on the right

Can we get the same base on both sides like we did in ▶ Example 3?

Unfortunately, it is difficult to find a number a so that $3 = 2^a$

And it is similarly difficult to write 2 as a power of 3.

Since our only method of solving exponential equations relies on writing both sides in the same base, we are stuck!

We need a new method!
