**Example:** Find solutions to the equation:

$$2^{(x+1)} = 2^{(3x-7)}$$

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a pone-to-one function.

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a pone-to-one function.

Which means that no two outputs can have the same input

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a pone-to-one function.

Which means that no two outputs can have the same input

In other words, if we have the same output we must have the same input

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a point-to-one function.

Which means that no two outputs can have the same input

In other words, if we have the same output we must have the same input Since,  $2^{(x+1)} = 2^{(3x-7)}$  they must have the same input

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a pone-to-one function.

Which means that no two outputs can have the same input

In other words, if we have the same output we must have the same input Since,  $2^{(x+1)} = 2^{(3x-7)}$  they must have the same input

In other words the two side must have the same exponent

x + 1 = 3x - 7

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a pone-to-one function.

Which means that no two outputs can have the same input

In other words, if we have the same output we must have the same input Since,  $2^{(x+1)} = 2^{(3x-7)}$  they must have the same input

In other words the two side must have the same exponent

x + 1 = 3x - 7

Now we simply have a linear equation that • we can solve

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a point-to-one function.

Which means that no two outputs can have the same input

In other words, if we have the same output we must have the same input Since,  $2^{(x+1)} = 2^{(3x-7)}$  they must have the same input In other words the two side must have the same exponent

x + 1 = 3x - 7

Now we simply have a linear equation that  $\cdots$  we can solve Solving the linear equation, we get: x = 4

**Example:** Find solutions to the equation:

 $2^{(x+1)} = 2^{(3x-7)}$ 

We saw from the graph of exponential functions that  $f(a) = 2^a$  is a pone-to-one function.

Which means that no two outputs can have the same input

In other words, if we have the same output we must have the same input Since,  $2^{(x+1)} = 2^{(3x-7)}$  they must have the same input In other words the two side must have the same exponent

x + 1 = 3x - 7

Now we simply have a linear equation that  $\bullet$  we can solve Solving the linear equation, we get: x = 4**Conclusion:** The solution to  $2^{(x+1)} = 2^{(3x-7)}$  is x = 4
